

Handling User Events

Introduction

Learn how to handle common user interactions, such as button clicks, input changes, and mouse events, in Blazor to create dynamic and responsive applications.

How to Handle Events in Blazor

1. Handle Button Click Events

Steps

- Add a button to your Blazor page and use the `@onclick` directive to attach an event handler.

```
<button @onclick="AddToCart">Add to Cart</button>
```

- In your code-behind or inline C#, create the event handler method:

```
private void AddToCart() {  
  
    cartCount++; // Increases the cart count each time the button is clicked.  
  
}
```

Result: When clicking the button, the AddToCart method will execute and update the cart count.

2. Handle Input Changes in Real Time

Steps

- Add an input field and use the `@oninput` directive to call a method whenever the input changes.

```
<input @oninput="UpdateSearch" placeholder="Search for products..." />
```

```
<p>You searched for: @searchQuery</p>
```

- Define the event handler method to process the input:

```
private void UpdateSearch(ChangeEventArgs e) {  
  
    searchQuery = e.Value.ToString(); // Updates the search query as the user  
types.
```

```
}
```

Result: The paragraph below the input will update in real-time with the text entered in the input field.

3. Handle Mouse Hover Events

Steps

- Add an element with a `@onmouseover` directive to trigger an action when the user hovers over it.

```
<div class="p-4 border rounded">
```

```
  <p @onmouseover="ShowProductDetails">Hover over the product</p>
```

```
</div>
```

```
<p>@productDetails</p>
```

- Create the method to handle the hover event:

```
private void ShowProductDetails() {
```

```
    productDetails = "Eco-friendly product with reusable packaging."; //
```

```
    Updates details on hover.
```

```
}
```

Result: When the user hovers over the text, additional product details will appear below it.

Tips for Success

- Reuse Handlers: Use one method for similar events across your application to reduce redundant code.
- Keep Code Organized: Separate UI markup and C# logic for maintainability.

Conclusion

By following these steps, you can easily handle user events in Blazor, enabling you to build interactive and user-friendly applications. Experiment with these techniques to enhance the interactivity of your projects!
