

Use Cases of Server-Side Blazor

Introduction

Server-side Blazor is a hosting model in the Blazor framework that enables developers to create interactive web applications using C# and .NET, where most application logic is executed on the server.

Key Concepts

- **Server-Centric Architecture:** In server-side Blazor, UI updates and logic execution occur on the server, communicated to the client via a real-time connection using SignalR.
- **Real-Time Updates:** SignalR allows instantaneous updates to the client browser without page reloads, enabling responsive applications.
- **State Management:** Server-side Blazor preserves user data across sessions, ensuring a consistent and seamless user experience.

Use Cases

- **Fast Load Times:** This is suitable for scenarios requiring quick initialization by reducing client-side processing and data transfer. Examples include dashboards and tools for frequent use.
- **Device Compatibility:** This is ideal for broad device support, including older devices without WebAssembly compatibility, such as public information sites or customer service tools.
- **Real-Time Applications:** Works well for apps needing instant updates, such as live reporting dashboards and collaborative tools.
- **Server-Controlled Logic:** Simplifies updates by managing changes on the server, immediately reflecting them on the client.

Conclusion

Server-side Blazor is an efficient solution for creating responsive, device-compatible applications with real-time capabilities. It is particularly suited for applications with dynamic updates and diverse user bases.
