

Implementing Navigation

Introduction

This guide helps you implement navigation in Blazor using routing, navigation links, and programmatic navigation.

Steps to Implement Navigation in Blazor

1. Define Routes Using the `@page` Directive

- Add `@page` at the top of a component file to define its route.
- Example: `@page "/home"` in `Home.razor` maps the `/home` URL to this component.

2. Set Up Dynamic Routes

- Use placeholders in the route to pass data through the URL.
- Example:

```
@page "/product/{id}"
```

```
[Parameter] public string Id { get; set; }
```

- This captures the `id` value from a URL like `/product/123` to display specific content.

1. Use `<NavLink>` for Clickable Navigation

- Create user-friendly navigation links:

```
<NavLink href="/home">Return to Home</NavLink>
```

- This directs users to the specified component without reloading the entire page.

1. Enable Programmatic Navigation

- Use the `NavigationManager` class for automatic redirection after an event.
- Example:

```
@inject NavigationManager NavManager
```

```
@code {
```

```
    private void NavigateToCart() {
```

```
NavManager.NavigateTo("/cart");
```

```
}
```

```
}
```

- This method navigates to `/cart` after processes like form submission.

Conclusion

Mastering Blazor's navigation ensures smooth, dynamic user experiences. Use the above steps to configure effective navigation in your applications.
